

On Tightness of Mutual Dependence Upperbound for Secret-key Capacity of Multiple Terminals

Chung Chan

Abstract—Csiszár and Narayan[3] defined the notion of secret-key capacity for multiple terminals, characterized it as a linear program with Slepian-Wolf constraints of the related source coding problem of communication for omniscience, and upper bounded it by some information divergence expression from the joint to the product distribution of the private observations. This paper proves that the bound is tight for the important case when all users are active, using the polymatroidal structure[6] underlying the source coding problem. When some users are not active, the bound may not be tight. This paper gives a counter-example in which 3 out of the 6 terminals are active.

ACKNOWLEDGMENT

I would like to thank Professor Lizhong Zheng for his guidance and inspiring comments; Baris Nakiboglu for his construction of s_i 's in the proof of Theorem 1 and for pointing out that intersection are also tight constraints in Proposition 2; Professor Imre Csiszár for clarifications of the topic during his visit at MIT; and, above all, my family for their support and encouragements.

I. INTRODUCTION

Consider a group of people with access to correlated discrete memoryless sources. The problem of communication for omniscience[3] (CO) asks how much authenticated public discussion is needed so that the active users in the group can recover all the sources reliably. The problem of secret-key generation[3] (SK) asks how much secret they can agree on.

Intuitively, the more correlated the sources are, the less public discussion is needed for CO because active users can learn the sources with their private observations as side information. With less information revealed in public, the active users can also share more secret. Are the maximum savings in public discussion and the amount of secret exactly the mutual dependence of the sources? How should one define such mutual dependence?

In [3], Csiszár and Narayan show that the secret-key capacity is equal to the maximum savings in public discussion, i.e. entropy rate of the sources minus the smallest rate of CO. While the active users need not attain omniscience before agreeing on a secret key, doing so guarantees certain universality result without loss of optimality. They then upper bound the capacity by some normalized information divergence[3, (26)] from the joint to the product distribution, which is commonly interpreted as mutual dependence of a set of random

variables.[6] As will be shown in the sequel, this mutual dependence upperbound is indeed tight for the case when all users are active. This gives an affirmative answer to the first question, and confirms the information divergence expression as a measure of mutual dependence. The equivalence is of theoretical interest and can simplify the exact computation of secret-key capacity in certain special cases as described in [3].

In the other case when some users are helpers, it is straightforward to show that the bound is tight for the 3-terminal case by an exhaustive test.¹ We have found, however, that the bound is loose for a 6-terminal counter-example with 3 active users. It is unclear if there exists a more general and ubiquitous mutual dependence expression that covers this case and other related problems.

II. PRELIMINARIES

Let $\mathcal{M} := \{1, \dots, m\}$ with $m \geq 2$ denote the set of all terminals and $\mathbf{X}_{\mathcal{M}} := (\mathbf{X}_1, \dots, \mathbf{X}_m)$ be the discrete multiple memoryless sources (DMMS), which is a sequence of random variables taking values from finite sets. The subset $\mathcal{A} \subset \mathcal{M} : |\mathcal{A}| \geq 2$ denotes the set of active users while its complement $\mathcal{A}^c$ is the set of helpers. From [3], the set of (strongly) achievable rate tuples of CO for $\mathcal{A}$ is,

$$\mathcal{R}(\mathcal{A}) = \{R_{\mathcal{M}} \in \mathbb{R}^m : \forall \mathcal{B} \in \mathcal{B}(\mathcal{A}), \text{SW}(R_{\mathcal{M}}, \mathcal{B}) \geq 0\}$$

where

$$\begin{aligned} \mathcal{B}(\mathcal{A}) &:= \{\mathcal{B} \subsetneq \mathcal{M} : \mathcal{B} \neq \emptyset, \mathcal{B} \not\supset \mathcal{A}\} \\ \text{SW}(R_{\mathcal{M}}, \mathcal{B}) &:= \sum_{j \in \mathcal{B}} R_j - h(\mathcal{B}) \\ h(\mathcal{B}) &:= H(\mathbf{X}_{\mathcal{B}} | \mathbf{X}_{\mathcal{B}^c}) \end{aligned}$$

Each element in $\mathcal{B}(\mathcal{A})$ corresponds to a Slepian-Wolf constraint of CO for $\mathcal{A}$. $\text{SW}(R_{\mathcal{M}}, \mathcal{B})$ is the constraint function on the rate tuple $R_{\mathcal{M}} := (R_1, \dots, R_m)$. h is the conditional entropy function of the DMMS. The Slepian-Wolf constraint is satisfied/tight/slack if $\text{SW}(R_{\mathcal{M}}, \mathcal{B})$ is $\geq/= />$ zero.

From the set of achievable rate tuples, two key quantities of interest, namely the smallest CO rate $R_{\text{CO}}(\mathcal{A})$ and secret-key capacity $C_{\text{SK}}(\mathcal{A})$, can be computed as follows.

$$(1a) \quad R_{\text{CO}}(\mathcal{A}) = \min_{R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})} \sum_{i=1}^m R_i$$

$$(1b) \quad C_{\text{SK}}(\mathcal{A}) = h(\mathcal{M}) - R_{\text{CO}}(\mathcal{A})$$

Manuscript written on May 20, 2008. Revised on Jun 15, 2008.

¹An exhaustive test by a computer program suggests informally that the bound is also tight for the 4-terminal case. The 5-terminal case is intractable.

Written in matrix form[3], $R_{\text{CO}}(\mathcal{A})$ is the solution to the following primal and dual linear programs by the Duality Theorem[4, p.130-132].

$$(2a) \quad R_{\text{CO}}(\mathcal{A}) = \min_{x: Ax \geq b} cx \quad (\text{primal})$$

$$(2b) \quad = \max_{y \geq 0: yA = c} yb \quad (\text{dual})$$

where A is an l -by- m incidence matrix of the Slepian-Wolf constraints;² b is the corresponding l -by-1 column vector of conditional entropies; c is a 1-by- m row vector of all 1's; x is a 1-by- m rate vector satisfying the Slepian-Wolf constraints $Ax \geq b$; and y is a 1-by- l non-negative weight vector.

Of particular interest is the following mutual dependence upperbound[3, (26)] on $C_{\text{SK}}(\mathcal{A})$.

$$(3) \quad I(\mathcal{A}) := \min_{2 \leq k \leq |\mathcal{A}|, (\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{A})} I(\mathcal{C}_1, \dots, \mathcal{C}_k)$$

where

$$\begin{aligned} I(\mathcal{C}_1, \dots, \mathcal{C}_k) &:= \frac{1}{k-1} \left(\sum_{i=1}^k H(X_{\mathcal{C}_i}) - H(X_{\mathcal{M}}) \right) \\ &= \frac{1}{k-1} D \left(P_{X_{\mathcal{M}}} \parallel \prod_{i=1}^k P_{X_{\mathcal{C}_i}} \right) \\ \mathcal{P}_k(\mathcal{A}) &:= \{ \{\mathcal{C}_i\}_{i=1}^k : \mathcal{C}_1 \cup \dots \cup \mathcal{C}_k = \mathcal{M}, \\ &\quad \forall i \neq j, \mathcal{C}_i \cap \mathcal{C}_j = \emptyset, \mathcal{C}_i \cap \mathcal{A} \neq \emptyset \} \end{aligned}$$

$\mathcal{P}_k(\mathcal{A})$ is the set of all k -partitionings of $\mathcal{M}$ such that each partition intersects $\mathcal{A}$. $I(\mathcal{C}_1, \dots, \mathcal{C}_k)$ is the mutual dependence with respect to the k -partitioning $(\mathcal{C}_1, \dots, \mathcal{C}_k)$. $D(\cdot \parallel \cdot)$ is the information divergence from the joint to the product distribution.[2] It is the well-known Shannon's mutual information in the 2-terminal case, and therefore commonly interpreted as mutual dependence for the multi-terminal case.[6] The goal of this paper is to confirm this heuristic interpretation by studying the tightness of the mutual dependence upperbound.

III. STATEMENT OF RESULTS

From the derivation of the mutual dependence upperbound (3), it is straightforward to see that tightness of the bound requires certain Slepian-Wolf constraints to be tight. The necessary and sufficient condition is as follows.

Proposition 1 (Tightness condition). $C_{\text{SK}}(\mathcal{A}) = I(\mathcal{A})$ iff there exists $(\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{A})$ with $2 \leq k \leq |\mathcal{A}|$ and $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})$ such that $\text{SW}(R_{\mathcal{M}}, \mathcal{C}_i^c) = 0$ for all $i \in \{1, \dots, k\}$.

Not only is this condition useful for a general exhaustive test for tightness, it is also fundamental for the subsequent proof of the main theorem. The idea is to look for a valid partitioning $(\mathcal{C}_1, \dots, \mathcal{C}_k)$ such that $C_{\text{SK}}(\mathcal{A}) = I(\mathcal{C}_1, \dots, \mathcal{C}_k)$. This happens iff $\mathcal{C}_i^c$'s are tight Slepian-Wolf constraints.

Now, suppose $\mathcal{B}_1$ and $\mathcal{B}_2$ are two tight Slepian-Wolf constraints. Are their union $\mathcal{B}_1 \cup \mathcal{B}_2$ and intersection³ $\mathcal{B}_1 \cap \mathcal{B}_2$ tight? The answer is affirmative as stated below due to the polymatroidal structure[6].

² l is the total number $|\mathcal{B}(\mathcal{A})|$ of constraints, which is $2^m - 2^{m-|\mathcal{A}|} - 1$.

³The tightness of the intersection is not essential in the proof of the main theorem.

Proposition 2 (Polymatroidal structure). For all $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})$ and $\mathcal{B}_1 \cup \mathcal{B}_2 \in \mathcal{B}(\mathcal{A})$, we have

$$\begin{cases} \text{SW}(R_{\mathcal{M}}, \mathcal{B}_1) = 0 \\ \text{SW}(R_{\mathcal{M}}, \mathcal{B}_2) = 0 \end{cases} \implies \begin{cases} \text{SW}(R_{\mathcal{M}}, \mathcal{B}_1 \cup \mathcal{B}_2) = 0 \\ \text{SW}(R_{\mathcal{M}}, \mathcal{B}_1 \cap \mathcal{B}_2) = 0 \end{cases}$$

When all users are active, the Duality Theorem and the induced tightness of the union of tight constraints implies the existence of the desired partitioning for tightness. This, however, does not extend to the case when some users are helpers. The bound is indeed loose for a particular 6-terminal counter-example. Hence, we have the following main theorem.

Theorem 1 (Tightness). When all users are active, we have

$$C_{\text{SK}}(\mathcal{M}) = I(\mathcal{M})$$

When some users are helpers, i.e. $\mathcal{A} \subsetneq \mathcal{M}$, there is a counter-example for which $C_{\text{SK}}(\mathcal{A}) < I(\mathcal{A})$ with strict inequality.

IV. INTERPRETATION OF MUTUAL DEPENDENCE

Why is $I(\mathcal{M})$ a measure of mutual dependence? In the 2-terminal case, it is simply the well-known Shannon's mutual information $I(X_1; X_2) := D(P_{X_1 X_2} \parallel P_{X_1} \circ P_{X_2})$. [2] But in the multi-terminal case, how can we interpret the normalization factor and the minimization over different partitionings?

Consider the sunflower example where $X_i = (Y, Z_i)$ for $i \in \mathcal{M}$. The core Y and the petals Z_i 's are mutually independent. For any k -partitioning $(\mathcal{C}_1, \dots, \mathcal{C}_k)$,

$$I(\mathcal{C}_1, \dots, \mathcal{C}_k) = \frac{1}{k-1} \left(\sum_{i=1}^k H(X_{\mathcal{C}_i}) - H(X_{\mathcal{M}}) \right) = H(Y)$$

since $H(X_{\mathcal{C}}) = H(Y) + \sum_{j \in \mathcal{C}} H(Z_j)$ for $\mathcal{C} = \mathcal{M}, \mathcal{C}_1, \dots, \mathcal{C}_k$. Thus, $I(\mathcal{M}) = H(Y)$ as expected. From this example, we see that the factor $1/(k-1)$ compensates for the over-counting of $H(Y)$ in the sum $\sum_{i=1}^k H(X_{\mathcal{C}_i})$, and that the optimal partitioning need not be unique.

Suppose $(\mathcal{C}_1, \dots, \mathcal{C}_k)$ is an optimal partitioning that achieves the minimum $I(\mathcal{M})$. Can we say that the random variables within the same partition are more correlated than those in different partitions? With the tightness result, we can recast the question in the CO setting as follows. Consider grouping users according to an optimal partitioning. If there is a private discussion that leads to omniscience within each group before the public discussion, i.e. user j in $\mathcal{C}_i$ knows the conglomerated sequence of $X_{\mathcal{C}_i}$, does it reduce the smallest CO rate? No because $(\{1\}, \dots, \{k\})$ is a valid partitioning that achieves the same mutual dependence of the set of conglomerated random variables. This means that attaining omniscience across different groups is the bottleneck of the CO problem. One does not need addition redundancy in rate to attain omniscience within each group. i.e. $\text{SW}(R_{\mathcal{M}}, \mathcal{C}_i^c) = 0$ for all $i \in \{1, \dots, k\}$ and some optimal $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{M})$. This gives an operational meaning of the optimal partitioning.

V. COUNTER-EXAMPLE

In this section, we describe a counter-example for which the mutual dependence upper bound $C_{\text{SK}}(\mathcal{A}) \leq I(\mathcal{A})$ is loose, i.e. satisfied with strict inequality, when some users are

helpers. Let $m = 6$, $\mathcal{A} = \{1, 2, 3\}$ and (Y_1, Y_2, Y_3, Y_4) be iid uniformly random bits. The DMMS $X_{\mathcal{M}}$ is defined below as the XOR $\oplus$ of every distinct pair of the random bits.

$$\begin{aligned} X_1 &:= Y_1 && \oplus Y_3 \\ X_2 &:= Y_1 && \oplus Y_4 \\ X_3 &:= && Y_3 \oplus Y_4 \\ X_4 &:= && Y_2 \oplus Y_3 \\ X_5 &:= && Y_2 \oplus Y_4 \\ X_6 &:= Y_1 \oplus Y_2 \end{aligned}$$

There are altogether $l = 55$ Slepian-Wolf constraints $\mathcal{B} \in \mathcal{B}(\mathcal{A})$. With some algebra, the conditional entropy function h can be simplified to the following expression that depends only on the cardinality of the constraint.

$$(4) \quad h(\mathcal{B}) = \begin{cases} 0 & \text{if } |\mathcal{B}| \in \{1, 2\} \\ 1 & \text{if } |\mathcal{B}| \in \{3, 4\} \\ 2 & \text{if } |\mathcal{B}| = 5 \end{cases}$$

Solving the linear program (1a) and applying (1b),

$$R_{\text{CO}}(\mathcal{A}) = \frac{9}{4} \implies C_{\text{SK}}(\mathcal{A}) = 1.75$$

which is achieved by the unique optimal rate tuple with

$$R_1 = R_2 = R_3 = \frac{1}{4} \quad R_4 = R_5 = R_6 = \frac{1}{2}$$

Appendix B describes how to compute and verify this solution.

It remains to show that $I(\mathcal{A}) > 1.75$. Consider a 3-partitioning $(\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3) \in \mathcal{P}_3(\mathcal{A})$ such that each partition has 2 elements. Applying (4) with $|\mathcal{C}_i^c| = 4$,

$$\begin{aligned} I(\mathcal{C}_1, \mathcal{C}_2, \mathcal{C}_3) &= h(\mathcal{M}) - \frac{h(\mathcal{C}_1^c) + h(\mathcal{C}_2^c) + h(\mathcal{C}_3^c)}{3 - 1} \\ &= 4 - \frac{1 + 1 + 1}{2} = 2.5 \end{aligned}$$

All other cases can be computed analogously as follows by enumerating the integer partitionings of 6.

integer partitioning	$\{ \mathcal{C}_1^c , \dots, \mathcal{C}_k^c \}$	$I(\mathcal{C}_1, \dots, \mathcal{C}_k)$
2 + 2 + 2	$\{4, 4, 4\}$	$4 - \frac{1+1+1}{2} = 2.5$
3 + 2 + 1	$\{3, 4, 5\}$	$4 - \frac{1+1+2}{2} = 2$
4 + 1 + 1	$\{2, 5, 5\}$	$4 - \frac{0+2+2}{2} = 2$
3 + 3	$\{3, 3\}$	$4 - (1 + 1) = 2$
4 + 2	$\{2, 4\}$	$4 - (0 + 1) = 3$
5 + 1	$\{1, 5\}$	$4 - (0 + 2) = 2$

We have the desired strict inequality that,

$$I(\mathcal{A}) = 2 > 1.75 = C_{\text{SK}}(\mathcal{A})$$

Appendix B gives an alternative argument that explains how this counter-example is constructed.

VI. PROOFS OF RESULTS

The mutual dependence upperbound is derived in [3] by removing certain Slepian-Wolf constraints as follows.

Proposition 3 (Mutual dependence upperbound).

$$(5) \quad C_{\text{SK}}(\mathcal{A}) \leq I(\mathcal{A}) \quad \forall \mathcal{A} \subset \mathcal{M} : |\mathcal{A}| \geq 2$$

Proof: Consider a partitioning $(\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{A})$.

$$\begin{aligned} \sum_{i=1}^k \sum_{j \in \mathcal{C}_i^c} R_j &= \sum_{i=1}^k \left[\sum_{j \in \mathcal{M}} R_j - \sum_{j \in \mathcal{C}_i} R_j \right] \\ &= (k-1) \sum_{j \in \mathcal{M}} R_j \\ (6) \quad \therefore \sum_{j \in \mathcal{M}} R_j &= \frac{1}{k-1} \sum_{i=1}^k \sum_{j \in \mathcal{C}_i^c} R_j \end{aligned}$$

Applying only the Slepian-Wolf constraints $\mathcal{C}_i^c$'s on $R_{\mathcal{M}}$ to the R.H.S. gives the desired bound. ■

The tightness condition then follows from the tightness of those Slepian-Wolf constraints used to derive the bound.

Proof of Proposition 1: Consider proving the ‘if’ case. Let $(\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{A})$ and $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})$ be such that $\text{SW}(R_{\mathcal{M}}, \mathcal{C}_i^c) = 0$ for all $i \in \{1, \dots, k\}$. Then, from (6),

$$\begin{aligned} \sum_{j=1}^m R_j &= h(\mathcal{M}) - I(\mathcal{C}_1, \dots, \mathcal{C}_k) \\ &\leq h(\mathcal{M}) - I(\mathcal{A}) \end{aligned}$$

By definition $R_{\text{CO}}(\mathcal{A}) \leq \sum_{i=1}^m R_i \leq h(\mathcal{M}) - I(\mathcal{A})$. Together with (5), we have $R_{\text{CO}}(\mathcal{A}) = H(X_{\mathcal{M}}) - I(\mathcal{A})$.

Consider proving the contrapositive of the ‘only if’ case. Suppose for all $2 \leq k \leq |\mathcal{A}|$, $(\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{A})$, $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})$, there exists $i \in \{1, \dots, k\}$ such that $\text{SW}(R_{\mathcal{M}}, \mathcal{C}_i^c) > 0$. Then, for all optimal $R_{\mathcal{M}}$,

$$R_{\text{CO}}(\mathcal{A}) = \sum_{j=1}^m R_j > H(X_{\mathcal{M}}) - I(\mathcal{A})$$

which implies $R_{\text{CO}}(\mathcal{A}) \neq H(X_{\mathcal{M}}) - I(\mathcal{A})$ as desired. ■

The polymatroidal structure[6] of the source coding problem can be used to prove that union and intersection of tight Slepian-Wolf constraints are tight as follows.

Proof of Proposition 2: Consider some $R_{\mathcal{M}} \in \mathcal{R}(\mathcal{A})$ and $\mathcal{B}_1 \cup \mathcal{B}_2 \in \mathcal{B}(\mathcal{A})$ such that $\text{SW}(R_{\mathcal{M}}, \mathcal{B}_1) = 0$ and $\text{SW}(R_{\mathcal{M}}, \mathcal{B}_2) = 0$. Then, $\mathcal{B}_1 \cup \mathcal{B}_2 \in \mathcal{B}(\mathcal{A})$ implies that $\mathcal{B}_1 \cup \mathcal{B}_2$, $\mathcal{B}_1$, $\mathcal{B}_2$ and $\mathcal{B}_1 \cap \mathcal{B}_2$ do not contains $\mathcal{A}$. If they are non-empty, they are all in $\mathcal{B}(\mathcal{A})$ by definition. Let $r(\mathcal{B}) := \sum_{i \in \mathcal{B}} R_i$ for all $\mathcal{B} \subset \mathcal{M}$. Then,

$$\begin{aligned} r(\mathcal{B}_1) &= h(\mathcal{B}_1) & r(\mathcal{B}_1 \cup \mathcal{B}_2) &\geq h(\mathcal{B}_1 \cup \mathcal{B}_2) \\ r(\mathcal{B}_2) &= h(\mathcal{B}_2) & r(\mathcal{B}_1 \cap \mathcal{B}_2) &\geq h(\mathcal{B}_1 \cap \mathcal{B}_2) \end{aligned}$$

To show that the union is a tight constraint,

$$\begin{aligned} h(\mathcal{B}_1 \cup \mathcal{B}_2) &\leq r(\mathcal{B}_1 \cup \mathcal{B}_2) = r(\mathcal{B}_1) + r(\mathcal{B}_2) - r(\mathcal{B}_1 \cap \mathcal{B}_2) \\ &\leq h(\mathcal{B}_1) + h(\mathcal{B}_2) - h(\mathcal{B}_1 \cap \mathcal{B}_2) \\ &\leq h(\mathcal{B}_1 \cup \mathcal{B}_2) \end{aligned}$$

where the last inequality is by the supermodularity of h . (see Lemma 1 in Appendix A) Hence, $r(\mathcal{B}_1 \cup \mathcal{B}_2) = h(\mathcal{B}_1 \cup \mathcal{B}_2)$. Similarly, $r(\mathcal{B}_1 \cap \mathcal{B}_2) = h(\mathcal{B}_1 \cap \mathcal{B}_2)$. The case when $\mathcal{B}_1 \cap \mathcal{B}_2 = \emptyset$ holds trivially. ■

The idea of the proof for the main theorem is to first obtain an initial set of tight Slepian-Wolf constraints from the dual linear program. Then, use the fact that union of tight Slepian-Wolf constraints are tight to construct the desired partitioning for the tightness condition.

Proof of Theorem 1: Consider some optimal solution $\mathbf{y}$ to the dual linear program (2b) with $\mathcal{A} = \mathcal{M}$. Let $t > 1$ be the number of non-zero entries in $\mathbf{y}$. Construct the 1-by- t row vector $\tilde{\mathbf{y}}$ by eliminating the zero entries in $\mathbf{y}$; and the t -by- m submatrix $\tilde{\mathbf{A}}$ of $\mathbf{A}$ by eliminating the corresponding rows, i.e. removing the i -th row if $y_i = 0$ for $i \in \{1, \dots, l\}$.

Let $\tilde{\mathbf{A}}_{\bullet j}$ be the j -th column of $\tilde{\mathbf{A}}$. Construct the desired partitioning $(\mathcal{C}_1, \dots, \mathcal{C}_k) \in \mathcal{P}_k(\mathcal{M})$ by partitioning $\tilde{\mathbf{A}}$ into classes of identical columns and let the t -by-1 vector $\mathbf{s}_i^T$ be the column of the i -th class. The precise construction is as follows.

Input: $\tilde{\mathbf{A}}$

Output: $k, (\mathbf{s}_1, \dots, \mathbf{s}_k)$ and $(\mathcal{C}_1, \dots, \mathcal{C}_k)$

$k := 1; \quad \mathcal{C}_1 := \emptyset; \quad \mathbf{s}_1 := \tilde{\mathbf{A}}_{\bullet 1}^T;$

for $j := 1$ **to** m **do**

if $\tilde{\mathbf{A}}_{\bullet j} = \mathbf{s}_i^T$ **for some** $i \leq k$ **then**
 Add j to $\mathcal{C}_i$;

else

$k := k + 1; \quad \mathcal{C}_k := \emptyset; \quad \mathbf{s}_k := \tilde{\mathbf{A}}_{\bullet j}^T;$

end

end

To argue that $k \geq 2$, note that $\tilde{\mathbf{A}}$ does not have any rows of all 1's nor rows of all 0's because $\mathcal{M}$ and $\emptyset$ are not Slepian-Wolf constraints. With $t > 1$, at least two columns of $\tilde{\mathbf{A}}$ are distinct. The other constraint that $k \leq m$ holds trivially.

It remains to argue that $\mathcal{C}_i^c$'s are tight Slepian-Wolf constraints in essence of the tightness condition in Proposition 1. As an immediate consequence of the Duality Theorem (see Lemma 2 in Appendix A), rows of $\tilde{\mathbf{A}}$ correspond to tight Slepian-Wolf constraints. Since unions of tight constraints are tight by the polymatroidal structure (see Proposition 2), it suffices to show that $\mathcal{C}_i^c$'s are unions of constraints corresponding to rows of $\tilde{\mathbf{A}}$.

To do so, define $\neg$ as elementwise negation and $\odot$ as the logical matrix multiplication, in which addition and multiplication are replaced by logical 'or' and 'and'. Then, $(\neg \mathbf{s}_i) \odot \tilde{\mathbf{A}}$ corresponds to taking union of constraints in $\tilde{\mathbf{A}}$ whose corresponding entry in $\mathbf{s}_i$ is 0. It suffices to show that $\mathbf{s}_i^T \odot \tilde{\mathbf{A}}$ indeed corresponds to $\mathcal{C}_i^c$, or equivalently, that $(\neg \mathbf{s}_{i'}) \odot \mathbf{s}_i^T = 1$.

Assume to the contrary that there exists $i \neq i'$ in $\{1, \dots, k\}$ such that $(\neg \mathbf{s}_{i'}) \odot \mathbf{s}_i^T = 0$ instead. Since $\mathbf{s}_i^T$'s are constructed from distinct columns of $\tilde{\mathbf{A}}$, there exists $j \neq j'$ in $\mathcal{M}$ such that,

$$(\neg \tilde{\mathbf{A}}_{\bullet j'})^T \odot \tilde{\mathbf{A}}_{\bullet j} = 0 \quad \text{but} \quad \tilde{\mathbf{A}}_{\bullet j'} \neq \tilde{\mathbf{A}}_{\bullet j}$$

This implies that the constraint of $\tilde{\mathbf{A}}_{\bullet j'}$ is a proper superset of that of $\tilde{\mathbf{A}}_{\bullet j}$. Since $\tilde{\mathbf{y}} > 0$,

$$\tilde{\mathbf{y}} \tilde{\mathbf{A}}_{\bullet j'} > \tilde{\mathbf{y}} \tilde{\mathbf{A}}_{\bullet j}$$

But this contradicts $\tilde{\mathbf{y}} \tilde{\mathbf{A}} = \mathbf{y} \mathbf{A} = \mathbf{1}$, which is the constraint of the dual linear program. This completes the proof. (See Section V for the counter-example.) ■

VII. CONCLUSION

The mutual dependence upperbound $I(\mathcal{M})$ on the secret-key capacity in [3] is proved to be tight for the case when

all users are active. This gives an operational meaning to the mutual dependence expression, and therefore confirms its heuristic interpretation as a measure of correlations among a set of random variables.

The proposed proof uses the polymatroidal structure in the source coding problem pointed out by [6]. Starting with an arbitrary solution to the dual problem (by the Duality Theorem in linear programming already mentioned in [3]), an initial set of tight Slepian-Wolf constraints is obtained. The desired set of tight Slepian-Wolf constraints is then derived using the polymatroidal structure.

As shown by the counter-example with 3 active users and 3 helpers, the mutual dependence upperbound need not be tight for the case when some users are helpers. Thus, the mutual dependence expression $I(\mathcal{A})$ in this case is not supported with the operational meaning of CO and SK, even though an exhaustive test shows that it is tight for the 3-terminal case and (informally with the help of a computer) for the 4-terminal case. It is unclear if there is a more general mutual dependence expression that cover this case or other problems related to the mutual dependence of a set of random variables.

APPENDIX A CLARIFICATIONS

Lemma 1 (Supermodularity). *For all $\mathcal{B}_1, \mathcal{B}_2 \subset \mathcal{M}$,*

$$h(\mathcal{B}_1) + h(\mathcal{B}_2) \leq h(\mathcal{B}_1 \cup \mathcal{B}_2) + h(\mathcal{B}_1 \cap \mathcal{B}_2)$$

Proof: Subtracting L.H.S. from R.H.S. gives,

$$\begin{aligned} & h(\mathcal{B}_1 \cup \mathcal{B}_2) + h(\mathcal{B}_1 \cap \mathcal{B}_2) - h(\mathcal{B}_1) - h(\mathcal{B}_2) \\ &= -H(\mathbf{X}_{\mathcal{B}_1^c \cap \mathcal{B}_2^c}) - H(\mathbf{X}_{\mathcal{B}_1^c \cup \mathcal{B}_2^c}) + H(\mathbf{X}_{\mathcal{B}_1^c}) + H(\mathbf{X}_{\mathcal{B}_2^c}) \\ &= -H(\mathbf{X}_{\mathcal{B}_1^c \cup \mathcal{B}_2^c} | \mathbf{X}_{\mathcal{B}_1^c \cap \mathcal{B}_2^c}) + H(\mathbf{X}_{\mathcal{B}_1^c} | \mathbf{X}_{\mathcal{B}_1^c \cap \mathcal{B}_2^c}) + H(\mathbf{X}_{\mathcal{B}_2^c} | \mathbf{X}_{\mathcal{B}_1^c \cap \mathcal{B}_2^c}) \\ &= I(\mathbf{X}_{\mathcal{B}_1^c}; \mathbf{X}_{\mathcal{B}_2^c} | \mathbf{X}_{\mathcal{B}_1^c \cap \mathcal{B}_2^c}) \end{aligned}$$

which is positive as desired. ■

Lemma 2 (Complementary slackness[4, p.135-136]). *Consider the primal (2a) and dual (2b) formulations for $R_{\text{CO}}(\mathcal{A})$. For all optimal solutions $\mathbf{x}$ and $\mathbf{y}$, $i \in \{1, \dots, l\}$, if $y_i > 0$, then the i -th row $\mathbf{A}_{i\bullet}$ of $\mathbf{A}$ corresponds to a tight Slepian-Wolf constraint, i.e. $\mathbf{A}_{i\bullet} \mathbf{x} = b_i$.*

Proof: By the (strong) Duality Theorem, $\mathbf{c} \mathbf{x} = \mathbf{y} \mathbf{b}$. Since $\mathbf{y} \mathbf{A} = \mathbf{c}$ for $\mathbf{y}$ to be feasible, we have $\mathbf{y} \mathbf{A} \mathbf{x} = \mathbf{y} \mathbf{b}$, or equivalently,

$$\sum_{j=1}^l y_j \mathbf{A}_{j\bullet} \mathbf{x} = \sum_{j=1}^l y_j b_j$$

Assume to the contrary that there exists $i \in \{1, \dots, l\}$ such that $y_i > 0$ and $\mathbf{A}_{i\bullet} \mathbf{x} \neq b_i$. Since $\mathbf{A} \mathbf{x} \geq \mathbf{b}$, and $\mathbf{y} \geq \mathbf{0}$, the L.H.S. of the last equation would instead be strictly larger than the R.H.S., which is a contradiction. ■

APPENDIX B COMPUTATIONS FOR THE COUNTER-EXAMPLE

In this section, we compute $R_{\text{CO}}(\mathcal{A})$ for the counter-example in Section V using the Multi-Parametric Toolbox[7] for Matlab. First, we initialize the toolbox to use an LP solver that always terminates at a vertex optimal solution.

```
% initialize the LP solver with CDD Criss-Cross
opt=mpt_init('lpsolver','cdd','abs_tol',1e-8);
```

The matrices for the linear program (2a) can be constructed manually as follows.

```
A=[
1 0 0 0 0 0;0 1 0 0 0 0;1 1 0 0 0 0;0 0 1 0 0 0;1 0 1 0 0 0;
0 1 1 0 0 0;0 0 0 1 0 0;1 0 0 1 0 0;0 1 0 1 0 0;1 1 0 1 0 0;
0 0 1 1 0 0;1 0 1 1 0 0;0 1 1 1 0 0;0 0 0 1 0 0;1 0 0 0 1 0;
0 1 0 0 1 0;1 1 0 0 1 0;0 0 1 0 1 0;1 0 1 0 1 0;0 1 1 0 1 0;
0 0 0 1 1 0;1 0 0 1 1 0;0 1 0 1 1 0;1 1 0 1 1 0;0 0 1 1 1 0;
1 0 1 1 1 0;0 1 1 1 1 0;0 0 0 0 1 1;1 0 0 0 0 1;0 1 0 0 0 1;
1 1 0 0 0 1;0 0 1 0 0 1;1 0 1 0 0 1;0 1 1 0 0 1;0 0 0 1 0 1;
1 0 0 1 0 1;0 1 0 1 0 1;1 1 0 1 0 1;0 0 1 1 0 1;1 0 1 1 0 1;
0 1 1 1 0 1;0 0 0 0 1 1;1 0 0 0 1 1;0 1 0 0 1 1;1 1 0 0 1 1;
0 0 1 0 1 1;1 0 1 0 1 1;0 1 1 0 1 1;0 0 0 1 1 1;1 0 0 0 1 1;
0 1 0 1 1 1;1 1 0 1 1 1;0 0 1 1 1 1;1 0 1 1 1 1;0 1 1 1 1 1;
1];
```

```
b=[
0 0 0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0 0 0 1 0 0 0 1 0,...
1 1 0 0 0 1 0 0 0 0 0 0 0 1 0 1 1 0 0 0 0 1 0 1 1 1 1 2 1 2 2
]';
```

```
c=[1 1 1 1 1 1];
```

We can then use the command `mpt_solveLP` to solve the primal and dual linear programs. To match the API, y is a column vector instead of a row vector, and $nRco$ is the negation of $R_{CO}(\mathcal{A})$.

```
% Primal:  $R_{CO} = \min_x c^* x$  subject to:  $-A^* x \leq -b$ 
[x, Rco] = mpt_solveLP(c', -A, -b);
```

```
% Dual:  $nRco = \min_y b^* y$  subject to:  $A^* y = c^*$ 
lb=zeros(size(A,1),1);
ub=Inf*ones(size(A,1),1);
[y, nRco] = mpt_solveLP(-b, [], [], A', c', [], [], lb, ub);
```

The optimal solution $x = [0.25 \ 0.25 \ 0.25 \ 0.5 \ 0.5 \ 0.5]$ of the primal achieves $R_{CO} = 2.25$. The optimal solution of the dual has non-zero entries equal to 0.25 at positions of the tight Slepian-Wolf constraints. One can check that $y(A^*x - b) \leq \text{opt.abs_tol}$ returns a sequence of all 0.25's, and $\text{sum}(A^*x - b) > \text{opt.abs_tol}$ is 0. Now, to verify that the computed x is indeed optimal (since the output from a computer cannot be used as a formal proof), one can check that x and y are both feasible and satisfy the primal/dual optimality criteria in Theorem 2.9 of [5, p.48]. This implies that both x and y are optimal, and $R_{CO}(\mathcal{A}) = 2.25$ as desired. The mutual dependence upperbound computed in Section V is therefore formally proved to be loose.

There is an alternative explanation that the bound is loose without calculating it explicitly. The underlying reasoning has guided the construction of the counter-example, and the proof of tightness in the case when all users are active. Consider the tightness condition in Proposition 1. If one can show that for all optimal solutions in $\mathcal{R}(\mathcal{A})$, there is no subset of $2 \leq k \leq |\mathcal{A}|$ tight Slepian-Wolf constraints whose complement partitions $\mathcal{M}$, then the mutual dependence bound is loose. For the particular optimal solution x , exactly six Slepian-Wolf constraints are tight. i.e.

$$\begin{array}{c} \tilde{A} := \\ \begin{bmatrix} 1 & 0 & 1 & 1 & 0 & 0 \\ 0 & 1 & 1 & 0 & 1 & 0 \\ 1 & 1 & 0 & 0 & 0 & 1 \\ 1 & 1 & 0 & 1 & 1 & 1 \\ 1 & 0 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 \end{bmatrix} \end{array} \quad \begin{array}{c} x := \\ \begin{bmatrix} 1/4 \\ 1/4 \\ 1/4 \\ 1/2 \\ 1/2 \\ 1/2 \end{bmatrix} \end{array} = \begin{array}{c} \tilde{b} := \\ \begin{bmatrix} 1 \\ 1 \\ 1 \\ 2 \\ 2 \\ 2 \end{bmatrix} \end{array}$$

where x is the optimal solution x ; Rows of $\tilde{A}$ corresponds to the tight Slepian-Wolf constraints; and elements of $\tilde{b}$ are the corresponding conditional entropies. Note that rows of $\tilde{A}$, has either one 0 or three 0's. For the complements of a subset of 2 or 3 Slepian-Wolf constraints to partition $\mathcal{M}$, the only possibility is to have two tight Slepian-Wolf constraints whose incidence vectors have three 0's. But there is no two such rows of $\tilde{A}$ having 0's at complementing positions. Thus, the bound is loose if x is the unique optimal solution, which can be shown using the PUFAS algorithm in [1] as follows.

We first express the primal linear program in equational form by introducing a slack variable for each constraint to take up the slack. Let x_s be the 55-by-1 column vector of slack variables. Then,

$$R_{CO}(\mathcal{A}) = \min_{Ax \geq b} cx = \min_{\substack{[A \ -I] \begin{bmatrix} x \\ x_s \end{bmatrix} = b, \\ \begin{bmatrix} x \\ x_s \end{bmatrix} \geq 0}} \begin{bmatrix} c & 0 \end{bmatrix} \begin{bmatrix} x \\ x_s \end{bmatrix}$$

where I is an identity matrix with matching dimensions. The vertex optimal solution x_1 of this equational form can be computed as follows.

```
% Solving the primal problem in equational form
ceq=[c zeros(1,size(A,1))];
Aeq=[A -eye(size(A,1))];
lbeq=zeros(size(Aeq,2),1);
ubeq=Inf*ones(size(Aeq,2),1);
[x1, Rco1] = mpt_solveLP(ceq', [], [], Aeq, b, [], [], lbeq, ubeq);
```

One can verify that $R_{CO1} = 2.25$, $x_1(1:6) = x$ and $x_1(7:61) = A^*x - b$ within the absolute tolerance. If the solution is not unique, there will be a different vertex optimal solution with at least one positive entry at the position where the corresponding element of x_1 is zero. Let d be the incidence row vector of 0's in x_1 . Maximizing d^*x subject to an additional constraint for optimality that $\begin{bmatrix} c & 0 \end{bmatrix} \begin{bmatrix} x \\ x_s \end{bmatrix}$ equals R_{CO1} gives an alternative solution if there is one. If the solution is unique, the optimal value would be 0, achieved by x_1 . This test can be implemented as follows.

```
% Verifying uniqueness of optimal solution x (i.e. show notUnique=0)
[x2, notUnique] = mpt_solveLP(-double(x1(1e-8)), [], [], ...
[Aeq; ceq], [b; Rco1], [], [], lbeq, ubeq);
```

One can check that $\text{notUnique} = 0$ and $x_1 = x_2$ within the absolute tolerance. This shows x is the unique optimal solution, and hence the mutual dependence bound is loose.
